

Agent Tools Documentation

Below is a comprehensive list of all the tools I have access to by default, along with their descriptions.

1. ask_permission

Use this tool to ask for permission after a failure due to insufficient permissions, specifically when you need additional permissions for file reads or writes after a terminal command or file operation encounters a permission error.

2. ask_question

Use this tool to ask the user one or more multiple-choice questions, with the goal of clarifying underspecified requirements, soliciting design feedback, or picking a solution from a list of options.

3. browser_subagent

Start a browser subagent to perform actions in the browser with the given task description. The subagent has access to tools for both interacting with web page content (clicking, typing, navigating, etc) and controlling the browser window itself.

4. generate_image

Generate an image or edit existing images based on a text prompt. The resulting image will be saved as an artifact for use. You can use this tool to generate user interfaces and iterate on a design.

5. grep_search

Use ripgrep to find exact pattern matches within files or directories. Results are returned in JSON format. Use the Includes option to filter by file type or specific paths to refine your search.

6. list_dir

List the contents of a directory, i.e. all files and subdirectories that are children of the directory. Directory path must be an absolute path to a directory that exists.

7. list_permissions

Use this tool to list all current permission grants. This helps you understand what resources you can access without prompting.

8. manage_task

Manage background tasks. Use this tool to list running tasks or interact with tasks that were sent to the background. Actions include: list, kill, status, send_input.

9. multi_replace_file_content

Use this tool to edit an existing file when making MULTIPLE, NON-CONTIGUOUS edits to the same file (i.e., changing more than one separate block of text).

10. read_url_content

Fetch content from a URL via HTTP request (invisible to USER). Converts HTML to markdown. No JavaScript execution, no authentication.

11. replace_file_content

Use this tool to edit an existing file when making a SINGLE CONTIGUOUS block of edits to the same file (i.e. replacing a single contiguous block of text).

12. run_command

PROPOSE a command to run on behalf of the user. Operating System: windows. Shell: powershell. Note that the user will have to approve the command before it is executed.

13. schedule

Schedule a one-shot timer or a recurring cron job that sends notifications in the background. Does not pause execution.

14. search_web

Performs a web search for a given query. Returns a summary of relevant information along with URL citations.

15. view_file

View the contents of a file from the local filesystem. Supports text files and some binary files (image, pdf, video, audio).

16. write_to_file

Use this tool to create new files. The file and any parent directories will be created for you if they do not already exist. Can optionally overwrite existing files.
